Case No. C09-2143 RS

**DECLARATION OF DANIEL W. WEBSTER
IN SUPPORT OF CITY AND COUNTY OF
SAN FRANCISCO'S OPPOSITION TO
PLAINTIFFS' MOTION FOR PRELIMINARY
INJUNCTION**

Hearing Date: Oct. 4, 2012
Time: 1:30 p.m.
Place: 450 Golden Gate Ave.
Courtroom 3 - 17th Floor
San Francisco, CA 94102

1 I, Daniel W. Webster, declare as follows:

2 1. For the past ten years, I have served as Co-Director of the Johns Hopkins Center for
3 Gun Policy. I have also been Deputy Director for Research for the Johns Hopkins Center for the
4 Prevention of Youth Violence since 2005.

5 2. I began my career in public safety research in 1985 as a Research Associate at the
6 University of Michigan and have focused most of my research on gun-related injuries and violence
7 during the past 23 years. I have a Masters of Public Health degree from the University of Michigan
8 and a doctorate in Health Policy and Management from the Johns Hopkins School of Public Health.
9 This graduate training included many advanced courses in epidemiology, research methods, and
10 statistical analysis.

11 3. Immediately prior to joining the faculty at Johns Hopkins, I directed a program on
12 violence research at the Washington (DC) Hospital Center. I joined the faculty of the Johns Hopkins
13 School of Public Health in 1992, and I am a tenured Professor of Health Policy and Management with
14 a joint appointment in the School of Education's Division of Public Safety Leadership. As noted
15 above, I am the Co-Director of the Johns Hopkins Center for Gun Policy and the Deputy Director for
16 Research for the Johns Hopkins Center for the Prevention of Youth Violence since 2005. I teach
17 graduate courses on violence prevention and research and evaluation methods at Johns Hopkins, direct
18 a PhD program in Health and Public Policy, and serve on the steering committee of a pre- and post-
19 doctoral training program in violence prevention research funded by the National Institutes of Health.

20 4. I have directed numerous studies related to gun violence and its prevention. I have
21 published 66 articles in scientific, peer-reviewed journals, the vast majority of these addressed some
22 aspect of violence and/or firearm injuries and their prevention. My CV, detailing these publications, is
23 attached as Exhibit 1 to this report.

24 5. I have been retained by the City and County of San Francisco to render expert opinions
25 in this case. I make this declaration on the basis of my training and expertise, the research discussed
26 herein, and the work that I have done in this case to date. This declaration does not constitute my final
27 written expert report. For my work in this case, I am being compensated at a rate of \$250 per hour.
28

1 **I. THE AVAILABILITY OF FIREARMS IN THE HOME INCREASES THE RISKS OF**
2 **SUICIDE, HOMICIDE, AND DEATHS FROM UNINTENTIONAL SHOOTINGS.**

3 6. It is my opinion that the availability of firearms in homes increases the risks of suicide,
4 homicide, and deaths from unintentional shootings. In the following paragraphs, I describe the
5 research that supports my opinion.

6 **A. Gun Availability and Suicides.**

7 7. Debates about gun policy tend to focus solely on violent crime, but policies and
8 personal decisions about keeping firearms in the home should take into consideration that sixty percent
9 of firearm-related deaths which occur in the U.S. are suicides.¹ A study which used data from the
10 National Mortality Follow-back Survey – a detailed survey of a systematic random sample of all
11 deaths in the U.S. in 1993 of persons age 15 years or older – focused on homicides and suicides. Data
12 from this study revealed that among the violent deaths which occurred within the home, suicides were
13 more than twice as common as homicides.² In San Francisco in 2009, suicides were more than twice as
14 common as homicides (97 vs. 40) and there were nearly as many firearm suicides as firearm homicides
15 (19 vs. 22).³ Because the research cited below indicates that the accessibility of firearms significantly
16 increases the risk of suicide, especially for adolescents and young adults, San Francisco has an interest
17 in reducing the availability of firearms within homes to children, adolescents, and unauthorized
18 individuals.

19 8. Furthermore, policies concerning how firearms are kept within the home should
20 consider that suicides within the home are more than twice as common as homicides in the home,
21 firearms are by far the most common method used in both causes of death, and the presence of
22 firearms in the home is associated with increased risk of both of these causes of death.

23
24 ¹ 18,735 of 31,347 firearm deaths in the U.S. in 2009. National Center for Injury Prevention
25 and Control. WISQARS Injury Mortality Reports, 1999-2009. Centers for Disease Control and
26 Prevention, Atlanta, GA. Accessed August 31, 2012.

27 ² Weibe DJ. Homicide and suicide risks associated with firearms in the home. *Annals of*
28 *Emergency Medicine* 2003;41:771-782.

³ Data generated from Centers for Disease Control and Prevention, National Center for Health
Statistics. Underlying Cause of Death 1999-2009 on CDC WONDER Online Database, released 2012.
Accessed August 31, 2012.

1 9. I reviewed several types of studies to arrive at my conclusions about the relationship
2 between firearm availability within the home and the risk of suicide, homicide, and unintentional
3 firearm deaths. The studies use different designs, study samples or populations, and analytic methods,
4 but the findings are consistent in showing a positive association between keeping firearms in the home
5 and the risk of suicide. The findings are also consistent with a widely accepted principle among
6 experts in the study and prevention of youth violence – that making the most lethal means of self-harm
7 less accessible will generally reduce risks for suicide and result in fewer suicides. This principle and
8 recommendation is referred to in many consensus documents such as recent reports on suicide
9 prevention by the U.S. Surgeon General and the National Action Alliance for Suicide Prevention⁴ and
10 the World Health Organization.⁵

11 **Household Studies**

12 10. There have been many case-control studies of households which measure the
13 association between the presence of firearms in the home and suicide, homicide, or unintentional
14 shooting death. Case-control studies involve comparisons between cases – those with the condition or
15 outcome of interest – and controls – those who do not have the condition or outcome of interest. Case-
16 control studies determine whether cases had greater exposure to a factor of interest, in this case being
17 in a home with a firearm, than did controls.

18 11. Nearly all of the case-control studies have shown a positive relationship between gun
19 ownership and suicides, with firearm ownership being associated with large increases in the risk of
20 suicide to household members. In a study of 803 suicides, 565 of which occurred within residences in
21 two metropolitan counties, Dr. Arthur Kellermann and colleagues⁶ reported that firearm ownership
22 was associated with a 4.7-fold increase in suicide after controlling differences between cases and
23 controls on a number of factors that are associated with suicide risks including age, sex, race, failure to

28 ⁶ Kellermann AL, Rivara FP, Somes G, et al. Suicide in the home in relation to gun ownership.
New England Journal of Medicine 1992;327:467-472.

1 graduate from high school, living alone, alcohol consumption, prior alcohol-related hospitalization,
2 current use of prescription medication for depression or mental illness, and use of illicit drugs.
3 Elevated suicide risks were observed only for suicides committed with a firearm. Individuals who
4 committed suicide by other means were no more or less likely to have had a firearm in their home. The
5 association between being in a home with a firearm and suicide was stronger for males (aOR = 6.4),
6 who would be much more likely to have acquired the firearm(s) kept in the home, than for females
7 (aOR = 3.3). Thus the data indicate that the risk of suicide was three times higher for women living in
8 homes with a firearm even though females are far less likely than are males to purchase and own
9 firearms. This substantial increase in suicide risk for females makes it difficult to attribute the
10 firearms-suicide association solely to suicidal intent prompting firearm ownership. The guns-suicide
11 association was also much stronger in situations where there was no prior history of mental illness
12 (aOR = 32.8) than when there was mental illness (aOR = 3.0).

13 12. Cummings and colleagues conducted a case-control study to examine the association
14 between legal purchases of handguns and suicide and homicide using data from a large population of
15 individuals enrolled in a health maintenance organization in metropolitan Seattle, Washington over a
16 13-year period.⁷ One advantage to this study over the one by Kellermann and colleagues is that it does
17 not rely upon data from proxy respondents for the cases but uses pre-existing administrative data to
18 measure risk factors including handgun purchases. The cases were 353 suicide victims and 117
19 homicide victims who were members of the HMO. Each case was matched with five control subjects
20 from the same HMO membership of the same age, sex, and ZIP code of residence. After controlling
21 for the individual's age, sex, the number of family members in the home, and neighborhood affluence
22 and education levels, the risk of suicide was 1.9 times higher for members of households where a
23 family member had legally purchased a handgun from a licensed gun dealer. Elevated risks for suicide
24 within homes with handgun purchases were exclusive to suicides committed with a firearm (RR =
25 3.1); however, there was no association between handgun purchase and suicide by other means. The
26

27 ⁷ Cummings P, Koepsell TD, Grossman DC, Savarino J, Thompson RS. The association
28 between the purchase of a handgun and homicide or suicide. *American Journal of Public Health*
1997;87:974-8.

1 association between handgun purchases and suicide risks were slightly higher for the person who
2 purchased the handgun (RR = 2.0, CI = 1.4 to 2.8) than for other family members (RR = 1.5, CI = 0.9
3 to 2.5). The elevated risk of suicide associated with handgun purchase history was greatest when a
4 handgun had been purchased less than a year before death, nevertheless, handgun purchases 5 or more
5 years prior were still associated with increased risk of suicide within the home (RR = 1.7, CI = 1.3 to
6 2.3). Furthermore, the median interval between the most recent handgun purchase by a household
7 member and a suicide was 10.7 years, indicating that in most instances the suicide victim did not
8 purchase a gun in order to complete a plan to commit suicide but rather used a firearm that had been
9 purchased years ago, sometimes by individuals other than the one who committed suicide.

10 13. In a nationally-representative study, based on data from the National Mortality Follow-
11 Back Survey and the National Health Interview Study, firearm ownership was associated with more
12 than a 3-fold increase in the risk of suicide for household members (adjusted odds ratio – aOR = 3.44,
13 CI = 3.06 to 3.86).⁸ The increased risk of suicide connected to guns in the home was exclusive to
14 suicides committed with a firearm. Risks for suicide by means other than firearms were slightly lower
15 among those living in a home with a gun, but much stronger association between guns and firearm
16 suicide led to a net increase in suicide by any means.

17 14. In the two case-control studies which examined the relationship between household
18 firearm access and suicide risk within age groups, the risk of suicide resulting from access to a firearm
19 in the home was elevated the most among adolescents and young adults. The positive association
20 between firearm ownership and suicides in the home in Kellermann et al.'s study indicated a 10-fold
21 increase in risk of suicide for those ages 24 and younger (aOR = 10.4, CI 1.6 to 68.8). In the national
22 study by Wiebe, age-group-specific suicide risk increases connected to household firearm ownership
23 were greatest for young adults ages 18-24 (aOR = 4.50, CI = 3.26 to 6.21).

24
25
26
27
28 ⁸ Weibe DJ. Homicide and suicide risks associated with firearms in the home. *Annals of
Emergency Medicine* 2003;41:771-782.

1 15. Ready access to the most lethal method for suicide is likely to greatly influence suicide
2 risks for adolescents for whom suicides are often very impulsive acts,⁹ and ready availability of the
3 most lethal means of self-harm determines whether an individual survives suicidal acts.^{10 11}
4 Adolescents and young adults are most likely to live in households with older adults, and it seems
5 unlikely that the firearms brought into the homes in cases where someone under age 25 committed
6 suicide would have been prompted by the victim’s intention to commit suicide. Research has shown
7 that firearms used by adolescent suicide victims were typically owned by parents or other family
8 members.¹²

9 16. Suicide by firearm is the third leading cause of death for persons ages 15 to 24.¹³ Local
10 studies have found that about two-thirds of adolescents who commit suicide with a firearm obtained
11 the gun from within their own homes or the home of a relative or friend¹⁴ and where the gun was
12 typically left unlocked.¹⁵

13 17. A series of studies of adolescent suicides in Western Pennsylvania have shown that
14 adolescents who died from suicides there were much more likely to have lived in homes with firearms
15 than adolescents in the following comparison groups – adolescents who had been hospitalized for
16 nonfatal suicide attempts and had psychiatric disorders,¹⁶ adolescents with psychiatric disorders who

of adolescent suicide victims with suicidal inpatients. *Archives of Gen Psychiatry* 1988;45:581-8.

1 had never attempted suicide,¹⁷ adolescents with a lifetime history of affective disorders who were
2 living at home with their families,¹⁸ adolescents in a demographically-matched group of community
3 controls without psychiatric conditions,¹⁹ and a general survey of adolescents drawn from the same
4 area as the suicides.²⁰

5 18. As a study design, case-control studies have limitations, perhaps most importantly the
6 difficulty in discerning the direction of cause (e.g., firearm ownership) and effect (e.g., suicide)
7 because suicidal intentions can cause someone to bring a gun into their home as well as having a gun
8 in the home contributes to a suicide. Yet the evidence indicates that suicide risks are elevated by
9 having firearms in the home for those who typically do not purchase or bring firearms into the home –
10 women and adolescents. Some have speculated that the consistently positive association between
11 firearm ownership and heightened risk of suicide might be due to unmeasured confounders – factors
12 which are correlated with firearm ownership that are causally related to suicide risks. However, there
13 does not appear to be higher rates of mental illness or suicidal ideation in homes with firearms
14 compared with homes with no firearms.^{21 22 23}

Cohort Studies

19. Cohort studies measure exposures (e.g., having firearms in your home) within a population and how those exposures are associated with subsequent outcomes (e.g., suicides). Wintemute and colleagues conducted a population-based cohort study to compare mortality among 238,292 persons who purchased a handgun in California in 1991 with that in the general adult population of the state. Mortality was examined for a period from the time of handgun purchase through the end of 1996. Sex-specific standardized mortality ratios (SMR – the ratio of the number of deaths among handgun purchasers to the number expected on the basis of age- and sex-specific rates among adults in California) were calculated for several age groups. During the first year after the purchase of a handgun, suicide was the leading cause of death among handgun purchasers. Handgun purchasers experienced suicide rates more than four times that of all Californians. The increased risk was attributable entirely to the excess risk of suicide with a firearm (SMR = 7.1). While the immediate risk for suicide among handgun purchasers is likely to reflect suicidal wishes prompting handgun purchases, handgun purchasers remained at increased risk for suicide by firearm throughout the six year study period, especially among women (SMR = 15.5 compared with 3.2 for men)²⁴.

Aggregate-Level Studies: Cross-Sectional Studies

20. The case-control and cohort studies referenced above measure the exposure and outcome at the level of individuals or households. In contrast, aggregate-level studies measure relationships between variables which are measured in the aggregate such as by city, county, state, or national. Several aggregate-level (mostly US state-level) studies have shown that populations with higher rates of firearm ownership tend to have significantly higher risks for firearm suicide and suicide by any means.^{25 26 27 28 29} Perhaps the most rigorous of these studies was led by Harvard physician and

²⁷ Miller M, Azrael D, Hemenway D. Firearm availability and suicide, homicide, and unintentional firearm deaths among women. *Journal of Urban. Health* 2002;79:26–38.

1 epidemiologist Matthew Miller who is considered by many to be the nation’s leading expert on the
2 relationship between the availability of lethal means of suicide and suicide risks. Miller and his
3 colleagues analyzed data on suicide rates across the 50 U.S. states and controlled for differences in
4 rates of poverty, urbanization, unemployment, mental illness, and drug and alcohol dependence and
5 abuse.³⁰ As would be expected if access to firearms in the home increased the risk for suicide, the
6 prevalence of household firearm ownership was positively associated with suicide rates (the higher the
7 prevalence of firearm ownership the higher the rate of suicide), and the positive association was
8 limited to suicides committed with firearms.

9 **Aggregate-Level Studies: Longitudinal Studies**

10 21. Most aggregate-level studies which examine the association between firearm ownership
11 and suicide have been cross-sectional, comparing suicide rates with gun ownership for a selected time
12 period. Studies based on longitudinal data, which compare *changes* in firearm ownership in relation to
13 *changes* in suicide rates are less vulnerable to potential threats to validity. Miller and colleagues
14 conducted such a study by examining annual changes in suicides in relation to annual changes in a
15 validated, surrogate measure of firearm ownership³¹ over the period of 1980 through 2002. After
16 statistically controlling for changes in age, unemployment, per capita alcohol consumption, and
17 poverty, for every 10 percent reduction in firearm ownership, there was a 4.2 percent reduction in the
18 rate of suicides with firearms and a 2.5 percent reduction in suicides by any means. There was no
19 relationship between changes in firearm ownership and changes in non-firearm suicides.³²

22 ²⁸ Miller M, Azrael D, Hemenway D. Firearm availability and unintentional firearm deaths,

changes in household firearm ownership and rates of suicide in the United States, 1981-2002. *Injury
Prevention* 2006;12:178-182.

1 **B. Gun Availability and Homicides.**

2 22. One third of all homicides in the U.S. occur in or around residential dwellings (Wiebe,
3 2003). In an in-depth study of homicides which occurred in or around residential dwellings in
4 geographically diverse metropolitan counties, of the cases in which the victim-perpetrator relationship
5 was known, 52 percent of the victims were murdered by a spouse, intimate partner, first-degree family
6 member, or roommate of the perpetrator, 37 percent were a friend or an acquaintance, and only 4
7 percent were strangers.³³ Thus, ready access to a firearm within the home when arguments or
8 altercations occur could determine whether such conflicts result in a homicide as well as a
9 community's homicide rate. This may be especially true for women's risk of homicide. One third of
10 all female homicide victims in the U.S. are killed by an intimate partner.³⁴ Twelve percent of all
11 violent crimes and 22.6 percent of all violent crimes committed against females are committed by the
12 victims' intimate partners (e.g., spouses, boyfriends),³⁵ who often live in the same household with the
13 victim.

14 **Household Studies**

15 23. Kellermann and colleagues used a case-control study design to examine the relationship
16 between firearm ownership and the risk of homicide in the home.³⁶ The cases were homicide incidents
17 which occurred within residences in three metropolitan counties and included 347 victims. Controls
18 were matched with cases by sex, race, age group, and neighborhood of residence. As noted above,
19 when the relationship between the victim and offender was known, most of the victims were related to,
20 intimate partners with, or roommates of the perpetrator, and only four percent were strangers. After
21 statistically controlling for differences due to home rental versus ownership, living alone, household

28 ³⁶ Kellermann AL, Rivara F, Rushforth NB, et al. Gun ownership as a risk factor for homicide
in the home. *New England Journal of Medicine* 1993;329:1084-1091.

1 members' involvements in fights within the home, history of arrest, and illicit drug use, firearm
2 ownership was associated with risk of homicide that was 2.7 times higher than in homes without
3 firearms (aOR = 2.7, 95% CI = 1.6 to 4.4) . The firearm-homicide relationship was strongest for
4 homicides committed by the victim's intimate partner or family member and indicated that the risk of
5 domestic homicide increased nearly eightfold for in homes with firearms (aOR = 7.8, 95% CI = 2.6 to
6 23.2).

7 24. A subsequent study drawing upon the same data in the Kellermann study focused on a
8 subset of the cases in which the person killed was a woman. In this study, there was a nearly fivefold
9 increased risk of a woman being the victim of a homicide associated with living in a home with
10 firearms.³⁷ In the majority of these cases, the victim was killed by an intimate partner or other family
11 member. I was a co-investigator of a subsequent case-control study of risk factors for intimate partner
12 homicide of women who had been in physically abusive intimate relationships. The study gathered
13 data in eleven cities and controlled for a wide range of risk factors including nature of prior intimate
14 partner violence, substance abuse, relationship characteristics, as well as abuser and victim
15 characteristics. This study found that the abuser's ownership of a firearm was associated with a
16 fivefold increase in risk of intimate partner homicide (aOR = 5.38). The study also examined
17 associations between factors present in the most serious incidents of intimate partner violence and
18 found that the abuser's use of a firearm increased the risk of lethal outcomes 41 times above that of
19 incidents in which a firearm was not involved.³⁸

20 25. In addition to examining the association between handgun purchases and suicide risks
21 to household members, the study of the HMO population cited above (Cummings et al. 1997) also
22 reported that the risk of homicide was more than twice as high (RR = 2.2) within households where
23 there had been one or more handguns purchased. The elevated risk for homicide was similar among
24 the handgun purchaser and his or her family members. A concern about case-control studies is that the

26 ³⁷ Baily JE, Kellermann AL, Somes G, Banton JG, Rivara F, Ruthforth NB. Risk factors for
violent death of women in the home. *Archives of Internal Medicine* 1997;15:777-782.

27 ³⁸ Campbell JC, Webster DW, Koziol-McLain J, et al. Risk factors for femicide within
28 physically abusive intimate relationships: Results from a multi-site case control study. *American
Journal of Public Health* 2003; 93:1089-1097.

1 risk of being a homicide victim could prompt gun acquisition and confound the estimated causal effect
2 of gun ownership on homicide risks. However, in Cummings study of the HMO population, the
3 median interval between first family handgun purchase and any homicide death was 11.3 years and the
4 risk of homicide was unrelated to how recently a handgun was purchased. Thus it seems unlikely that
5 the association measured is due to immediate homicide risks prompting gun ownership.

6 26. Wiebe's (2003) nationally representative study of the risk of violent death associated
7 with the presence of guns in the home demonstrated a positive association between living in a home
8 with at least one firearm and homicide victimization. Overall, the odds of a gun in the home was 41
9 percent higher among victims of homicide compared with demographically-matched controls. The
10 positive association between firearm ownership and homicide risk was greater for females (aOR =
11 2.72) than for males (aOR = 1.23). Twenty-nine percent of the homicides of male victims and 55
12 percent of homicides of females occurred in the home or private area around the home. Thus, while
13 adult males more commonly bring firearms into the home (male:female ratio of gun ownership is
14 between 3 and 4 to 1),³⁹ they are more commonly victimized outside the home. In contrast, females
15 suffer increased risk within their own homes when males bring firearms into the home.

16 27. While prior case-control studies examined the association between gun ownership and
17 homicide victimization, criminologists Kleck and Hogan conducted a national case-control study in
18 which the outcome of interest was homicide perpetration. Data from their cases came from the U.S.
19 Census Bureau's Survey of State Prison Inmates of 1991 who had committed a homicide as an adult
20 between 1980 and 1991. Controls were taken from the General Social Survey of the U.S. population.
21 They found gun ownership was positively associated with homicide perpetration. After statistically
22 controlling for age, sex, race, Hispanic ethnicity, marital status, personal income, education, military
23 veteran status, and having a child less than 18 years of age, the odds that a gun owner would commit a
24 homicide was 1.36 times higher than the odds of a nongun owner committing a homicide after
25 controlling for confounders.⁴⁰ Although the strength of the association between gun ownership and

Social Problems 1999;46:275-293

1 homicide perpetration risk was lower than was observed in the case-control studies of homicide
2 victimization, the direction of the association was consistent with the other studies.

3 **Cohort Studies**

4 28. Wintemute's study of the mortality risks of a cohort of legal handgun purchasers in
5 California relative to the general population of Californians with the same age and sex distribution
6 examined risks for homicide as well as for suicide. The risk being a victim of homicide with a firearm
7 was twice as high among women handgun purchasers relative to Californian women of the same age,
8 but was lower among men who legally purchased firearms (SMR = 0.8). I suspect that the elevated
9 risk for women was due to the fact that women are more likely to be killed by an intimate partner or
10 family member who might have access to a firearm kept in the woman's home whereas men are more
11 commonly murdered on the street by an acquaintance or stranger.

12 **Aggregate-Level Studies: Cross-Sectional Studies**

13 29. Miller and colleagues conducted a study to assess the cross-sectional association
14 between the prevalence of firearms in the home and homicide rates at the state level. The researchers
15 statistically controlled for differences across states in rates of aggravated assault, robbery,
16 unemployment, urbanization, per capita alcohol consumption, and economic resource deprivation.
17 States with higher rates of household firearm ownership had significantly higher homicide
18 victimization rates for men, women and children. Differences in the prevalence of household firearm
19 ownership were associated with proportionately similar differences in rates of homicide committed
20 with firearms. Consistent with the hypothesis that the positive association between gun ownership and
21 homicide was due to gun availability and not to differences in the propensity for violence between gun
22 owners and people who do not own guns, non-gun homicide victimization was not associated with
23 firearm ownership.⁴¹ In my opinion, this study might understate the cross-sectional relationship
24 between firearm ownership and homicide rates because the statistical models control for crimes that
25 could themselves be caused by higher levels of gun ownership (aggravated assaults and robberies).

27 ⁴¹ Miller M, Hemenway D, Azrael D. State-level homicide victimization rates in the US in
28 relation to survey measures of household firearm ownership, 2001-2003. *Social Sciences & Medicine*
2007;64:656-64.

1 These findings were consistent with those of similar prior studies that relied on a surrogate measure of
2 gun ownership rather than direct survey data^{42 43} and a subsequent study using similar data.^{44 45}

3 30. Miller and colleagues also published studies on the association between gun availability
4 and homicide of children ages 5 – 14 years⁴⁶ and homicides of women ages 20 and over.⁴⁷ In each
5 case, they report statistically significant positive associations between gun availability and firearm
6 homicide rates at the state-level, but no gun availability effects on non-firearm homicides. It is worth
7 noting that the groups Miller and colleagues studied – children and women – do not typically bring a
8 firearm into the home. Therefore positive associations between gun availability and homicide risks are
9 unlikely to be due to individuals being motivated by their own risk of homicide to acquire a gun.

10 **Aggregate-Level Studies: Longitudinal Studies**

11 31. Longitudinal study designs are generally preferable to cross-sectional studies because
12 they can ascertain temporal relationships between variables. This is important for studying the

18 ⁴⁵ Kleck and Patterson analyzed cross-sectional data for 170 U.S. cities with populations of
19 100,000 or more and report that gun ownership has no impact on homicide (Kleck G, Patterson EB.
20 The impact of gun control and gun ownership levels on violence rates. *Journal of Quantitative*
21 *Criminology* 1993;9:249-288). To address the concern that cross-sectional associations between gun
22 ownership and homicide could be due to higher homicide rates prompting increased gun ownership for
23 protection, the researchers used a two-stage least squares regression approach to the analyses which
24 involves using an instrumental variable in the first stage to estimate gun ownership levels absent any
25 effects from homicide rates. But this analytic approach is contingent upon the instrumental variable
being used to measure gun ownership meeting several conditions that are typically difficult to meet. A
detailed criticism of Kleck and Patterson’s study correctly points out that Kleck and Patterson failed to
provide common statistical tests to confirm that the instrumental variable he used met these conditions.
Alba RD, Messner SF. Point Blank and the Evidence: A Rejoinder to Gary Kleck. *Journal of*
Quantitative Criminology 1995;11:425-428. Thus, the validity of Kleck and Patterson’s findings are
unclear.

unintentional firearm deaths among women. *Journal of Urban Health* 2002;79:26-38.

1 relationship between gun ownership because gun ownership may affect homicide risks and homicide
2 risks can affect firearm acquisition. McDowall examined changes in two proxy measures for gun
3 ownership – the proportion of suicides committed with a firearm and the proportion of robberies
4 committed with a firearm – to study the temporal relationship between firearm availability and
5 homicide rates in Detroit. Using methods to negate reverse causality and statistically controlling for
6 changes in racial composition of the city, the proportion in the high-risk 15-24 year age group, the
7 homicide clearance rate lagged by 1 year, and the robbery rate, gun ownership was positively
8 associated with Detroit’s homicide rate. Licenses issued to purchase handguns were also positively
9 associated with homicide rates.⁴⁸

10 32. In a similar study, Sorenson and Berk examined temporal relationships between
11 handgun sales (lagged one year to avoid concerns of reverse causation) and age-, sex-, and race-
12 specific homicide rates after controlling for racial composition, cohort size, beer sales, unemployment,
13 and migration for the period 1972 – 1993. Lagged handgun sales were positively associated with
14 homicide rates for males of every age group and race/ethnicity; however, they found no relationship
15 between handgun sales and homicide victimization of females.⁴⁹

16 33. Magaddino and Medoff examined data for the years 1947 – 1977 and found that, while
17 new guns manufactured and imported did not predict homicide rates, the *cumulative* number of
18 handguns available was positively associated with homicide rates.^{50 51} A weakness of studies of this

23 Pages 225-258 in DB Kates(ed), *Firearms and Violence*. Cambridge, MA: Ballinger, 1984.

24 ⁵¹ Kleck conducted two time-series studies to examine the relationship between guns and
25 homicide rates for the United States as a whole. The first study examined data for 1947 – 1973 and
26 used a commonly used statistical approach (two-stage least-squares regression) to disentangle
27 potentially reciprocal relationships between variables such as homicides and gun sales while
28 controlling for other variables related to both. His findings indicated that increases in the number of
guns manufactured or imported into the U.S. predicted higher U.S. homicide rates. In his second study
of this type, Kleck extended the data from this first study through 1978, added additional explanatory
variables including robbery rates to his statistical models, and used a four-equation simultaneous
model. His analyses indicated that increases in the number of guns manufactured or imported did not
predict changes in homicides; however, there was a positive association between guns manufactured
or imported and homicide rates if robbery rates were not included as an explanatory variable.

1 type is that the studies aggregate data over the entire United States, ignoring considerable variation at
2 state and local levels in gun sales and homicides.

3 34. In his book *More Guns, Less Crime*, John Lott, Jr. used state-level data on gun
4 ownership from exit polling data following the 1988 and 1996 presidential elections and reported a
5 negative relationship between gun ownership and homicide rates (suggesting that measured increases
6 in gun ownership led to decreases in homicide rates) over these two time periods.⁵² However, the
7 polling data Lott used only included actual voters who represent a non-random minority of the actual
8 adult population. His findings on changes in gun ownership are inconsistent with rigorous surveys
9 designed to accurately reflect conditions across all households that show gun ownership declining
10 from 1988 to 1996 (e.g., the University of Chicago's General Social Survey)⁵³.

11 35. In a study examining longitudinal data at the state and county levels, economist Mark
12 Duggan examined the dynamic relationship between gun ownership and crime over the period 1980-
13 1998 using state- and county-level data on a validated proxy for gun ownership. To avoid the
14 potential for reverse causality (higher homicide rates prompting higher rates of gun ownership),
15 Duggan examines the relationship between gun ownership lagged by one year ($t - 1$) with homicide
16 rates. Data from this study demonstrate that changes in gun ownership were positively related to
17 changes in homicide rates. As with other studies, the gun ownership-homicide relationship is due
18 entirely to gun ownership's effects on homicides committed with firearms. Gun ownership does not
19 predict rates of homicides committed without firearms. This pattern of findings was the same for
20 analyses done at the state level and at the county level. Duggan estimates that a third of the dramatic
21

22 Kleck's findings have little relevance to the question of the relationship between the
23 availability of firearms and homicide rates because changes in the number of guns manufactured or
24 imported in a given year should have little effect on the prevalence of firearms within homes. It could
25 take years for many of those guns to be sold and when they are sold, divergent trends in gun sales,
26 which are going up, and the prevalence of gun ownership, which is going down, suggest that they are
27 most commonly sold to people who already own guns (Violence Policy Center. *The Shrinking
28 Minority: The Continuing Decline of Gun Ownership in America.*
<http://www.vpc.org/studies/ownership.pdf>).

Research Center, University of Chicago, May 2007.

1 reductions in firearm homicide rates relative to changes in nonfirearm homicide rates which occurred
2 from 1993 to 1998 could be attributed to declines in the fraction of homes with firearms.⁵⁴

3 36. Noted economists and experts on gun policy, Philip Cook and Jens Ludwig, analyzed
4 20 years of state- and county-level data and also find a significant positive association between gun
5 availability and homicides with the relationship being exclusive to homicides committed with a
6 firearm. They estimate elasticities (the percentage change in homicides for every one percent change
7 in gun ownership) of +.1 to +.3 between gun ownership and homicides.⁵⁵

8 **C. Gun Availability and Deaths from Unintentional Shootings.**
9 **Household Studies**

10 37. To my knowledge, there has been only one study which has examined the relationship
11 between firearms in the home and the risk of unintentional firearm deaths. In this study, Wiebe used
12 data from a nationally representative survey – the 1993 National Mortality Followback Survey and
13 1994 National Health Interview Study (NHIS) – and a case-control study design to assess the
14 association between the presence of firearms in the home and risks of death from an unintentional
15 shooting. Cases consisted of 84 persons killed as a result of an unintentional shooting. Each case was
16 matched with up to 20 controls from the NHIS matched by sex, age group, race, and region of
17 residence and the analyses statistically controlled for any differences between the cases and controls
18 with respect to marital status, education level, and annual family income. The risk of an unintentional
19 shooting death was 3.7 times higher within homes with any firearm. Elevated risks were greatest, more
20 than a fivefold increase in risk for unintentional shooting death (RR = 5.3), in homes that kept only
21 handguns.⁵⁶ Keeping only handguns and not long guns, should be more likely to be the case for gun
22 owners in urban settings such as San Francisco.

Aggregate-Level Studies

1
2 38. I found only one aggregate-level study designed to assess the relationship between
3 firearm availability and the risk of death from an unintentional shooting. Miller and colleagues (2001)
4 studied the association between a state's rate of deaths due to unintentional shootings and the
5 prevalence of firearms. They found a very strong positive relationship between measures of firearm
6 availability and the rate of deaths from unintentional shootings. This positive relationship was
7 strongest for young children and teens.⁵⁷

8 **II. LOCKED STORAGE OF FIREARMS REDUCES THE RISK OF SUICIDE, HOMICIDE, AND DEATHS FROM UNINTENTIONAL SHOOTINGS.**

9 39. It is my opinion that keeping firearms locked up or locked with a trigger guard reduces
10 the risks associated with keeping firearms in the home. In the following paragraphs, I describe the
11 research that supports my opinion.

12 40. Data from Kellermann et al.'s study of risk factors for suicide within the home suggest
13 that safe gun storage practices reduce the risk of suicide within the home. The adjusted odds ratios
14 contrasting risks compared with similar households with no firearms clearly show a progression of
15 increasing risk with increasing ease of access – all guns locked up (aOR = 2.4), all guns stored
16 unloaded (aOR = 3.3), any gun left unlocked (aOR = 5.6), and any gun kept loaded (aOR = 9.2) the
17 condition under which guns would be most readily available for misuse. Thus the storage condition
18 which increased suicide risks the least above that of having no firearm in the home was storing all
19 guns locked up as is directed by the San Francisco ordinance in question.

20 41. Safe storage of firearms is likely to be particularly important for protecting teens from
21 killing themselves or others. Groups as diverse as the National Rifle Association and the American
22 Academy of Pediatrics recommend that gun owners store their guns so that they are inaccessible to
23 unauthorized persons including children and teens.^{58 59,}

Keeping-Children-Safe.aspx](http://www.healthychildren.org/English/safety-prevention/all-around/Pages/Gun-Safety-Keeping-Children-Safe.aspx). Accessed August 3, 2011.

1 42. Grossman and colleagues conducted a case-control study to assess the relationship
2 between firearm storage practices and adolescents' risk of suicide and unintentional shootings. They
3 collected data for cases from households where a youth less than 18 years of age was killed as a result
4 of a suicide or unintentional shooting and examined these deaths in 37 counties in the states of
5 Washington, Oregon, and Missouri in addition to nonfatal self-inflicted or unintentional shooting
6 victims treated at trauma centers in Seattle, Spokane, and Tacoma, Washington and Kansas City,
7 Missouri. Cases included 82 self-inflicted shootings (95% of which were fatal) and 24 unintentional
8 shootings (50% of which were fatal). Controls were identified through random surveys of the counties
9 where the cases were drawn and consisted of households where at least one firearm was kept in or near
10 (e.g., garage) the home. Data from this study indicate that the risk of self-inflicted and unintentional
11 firearm injuries was about 70 percent lower in gun-owning homes where firearms were stored locked
12 up and unloaded compared with homes where guns were not stored locked up and unloaded. The
13 relationship between gun storage practices and firearm deaths to adolescents was similar for suicide
14 and unintentional shootings.⁶⁰

15 43. Using data from statewide surveys of health and safety practices conducted by the
16 Centers for Disease Control and Prevention, which included questions about firearm ownership and
17 storage practices, Miller and colleagues conducted a state-level study to assess the relationship
18 between firearm storage and rates of death from unintentional shootings. Controlling for the
19 prevalence of guns in the home as well as urbanization and poverty levels, states in which it was less
20 common to store firearms unlocked and unloaded had significantly lower rates of unintentional firearm
21 deaths. The researchers contrasted data between the six states with the highest percentage of
22 individuals living in households with loaded firearms with the ten states where this practice was most
23 common. Although the six states with the highest prevalence of exposure to loaded firearms within the
24 home had less than half as many people and fewer people exposed to firearms than was the case with
25 the 10 states with the lowest percentage in homes with a loaded firearm, there were more than twice as
26

27 ⁶⁰ Grossman DC, Mueller BA, Riedy C, Dowd MD, Villaveces A, Prodzinski J, Nakagawara J,
28 Howard J, Thiersch N, Harruff R. Gun storage practices and risk of youth suicide and unintentional
firearm injuries. *Journal of the American Medical Association*. 2005 Feb 9;293(6):707-14.

1 many unintentional shooting deaths to youth under age 18 years than in the ten states where living in a
2 home with a loaded firearm was least common.⁶¹

3 44. Other than Kellermann et al.'s study connecting increasing ease of access to guns with
4 increasingly elevated risk of suicide among adults and showing that keeping all guns locked up
5 attenuated the increased risk more than other storage options, no other study specifically examined the
6 relationship between firearm storage and reduced risks of suicide, homicide, and unintentional
7 shootings among adults. Nonetheless, it is reasonable to believe that a protective effect from locked
8 storage would be found in any instance of firearm violence that is impulsive or spontaneous.
9 California's CAP law covers youth under age 18, but San Francisco's safe storage requirements which
10 extend to all adults should have some protective effects, especially for youth ages 18-24 where prior
11 studies have shown substantial increased suicide risks associated with access to firearms. Many young
12 adults live in homes with parents or with other adults who may own guns. Requirements to store
13 firearms locked up should be protective to young adults in these situations.

14 **III. POLICIES THAT REDUCE THE AVAILABILITY OF FIREARMS REDUCE
15 FIREARM-RELATED MORTALITY.**

16 45. It is my opinion that policies that reduce the availability of firearms reduce firearm-
17 related mortality. In the following paragraphs, I describe the research that supports my opinion.

18 46. In the United States, most gun control laws are not overly restrictive with respect to the
19 eligibility to legally purchase and possess firearms and have numerous loopholes which can diminish
20 the ability of the laws to keep guns from prohibited individuals. As such, most U.S. gun control laws
21 have minimal impact on the gun ownership. The most restrictive and rigorous gun control laws are
22 permit-to-purchase licensing laws which allow law enforcement agencies (usually local agencies)
23 issuing permits to purchase firearms to use their discretion in issuing these permits. These states also
24 have some of the most stringent nondiscretionary requirements for issuing permits to purchase
25 firearms. These three states have among the lowest rates of household gun ownership.

26
27
28 ⁶¹ Miller M, Azrael D, Hemenway D, Vrinotis M. Firearm storage practices and rates of
unintentional firearm deaths in the United States. *Accident Analysis & Prevention* 2005;661-667.

47. The data in the table below contrast these three states' firearm ownership and age-adjusted suicide rates among non-Hispanic Whites with that of the nation as a whole. Thus, the data presented control for three demographic factors associated with suicide rates – age, race, and ethnicity. The data indicate that the prevalence of firearms within homes is less than half as high as the national average and suicide rates for non-Hispanic White were 39% to 51% lower than the national average. The two right-hand columns present data on homicide rates for non-Hispanic whites and Blacks in large central metro counties where violent crime tends to be highest and therefore the availability of firearms most critical. For non-Hispanic Whites, homicide rates in these three states with low gun prevalence were 33% to 42% lower than for the nation overall. For Blacks, homicide rates were 8% to 45% lower than the national average. Though these data do not prove that policies which reduced the prevalence of firearms in homes led to fewer suicides and homicides, it is consistent with that thesis.

Table 1. Prevalence of household firearm ownership (2001), statewide age-adjusted suicide rates, and age-adjusted homicide rates for large central metro counties (2002 - 2004) for selected demographic groups in the three states with the most restrictive laws pertaining to permits to purchase a handgun by allowing local law enforcement discretion in issuing permits in comparison to U.S. totals.

	household gun prevalence, 2001 %	age-adjusted suicide rates – non-Hispanic Whites, 2002-2004 ⁱ	age-adjusted homicide rates – non-Hispanic Whites, 2002-2004 ⁱ	age-adjusted homicide rates – Blacks, 2002-2004 ⁱ
New York	18.0	7.6	2.2	15.1
New Jersey	12.3	6.3	2.5	25.5
Massachusetts	12.6	7.3	1.9	18.7
United States	31.7	12.8	3.3	27.6

ⁱper 100,000 population per year

48. A recent study more formally examines the relationship between different types of gun policies and state's suicide rates from 1995 through 2004. The study statistically controls for differences in educational attainment, income, alcohol consumption, proportion of the population over age 65, and the proportion of the population that is non-Hispanic and white. Some models control for the popularity of sports shooting by using hunting licenses per capita as a covariate in the regression models. The study found that permit-to-purchase licensing and bans on minors purchasing firearms –

1 policies likely to reduce population-level gun availability – were negatively associated with suicide
2 rates.⁶²

3 49. In 1997, Austria adapted its firearms laws by adding several new regulations and
4 restrictions. Individuals seeking to obtain a firearm had to specify a reason, and the legal criteria for
5 obtaining a category B weapon (handguns, semi-automatic firearms or repeating firearms) for the first
6 time would include psychological testing, being at least 21 years of age, and passing a background
7 check. Particularly relevant to the San Francisco ordinance, the new law mandated safe storage of
8 firearms and a three-day waiting period for long gun acquisitions. An evaluation of Austria’s 1997 gun
9 laws found that following the adoption of the law, both firearm suicides and firearm homicides fell
10 sharply as licenses to acquire firearms dropped precipitously. There was no evidence of a significant
11 substitution to other methods of suicide.⁶³

12 50. Between 1996 and 1998, Australia implemented a number of reforms to its gun laws
13 which appreciably affected firearm availability in that country. In addition to banning semi-automatic
14 and pump-action rifles and shotguns with government buybacks, all firearms were required to be
15 registered to their licensed owners, private firearm sales were prohibited, and each gun transfer
16 through a licensed gun dealer would be approved only if police were satisfied that the applicant had
17 genuine and special reason for ownership. An evaluation of the effects of these policies revealed that
18 the new firearms restrictions were associated with significant reductions in homicides and suicides and
19 that there was no evidence of a significant method substitution effect. Prior to these policies going into
20 effect, firearm homicides were trending downward at a rate of 3 percent per year. After the policies
21 were introduced, firearm homicides declined at a rate of 7.5 percent per year. Similarly, firearm
22 suicides had been trending downward prior to the legal changes at a rate of 3 percent per year and the
23 downward trend increased to 7.4 percent per year.⁶⁴

firearm deaths, firearm suicides, and a decade without mass shootings. *Injury Prevention*. 2006;
12:365-72.

1 51. In October 2003, Brazil enacted several measures to strengthen the nation’s gun control
2 laws including making it illegal for individuals to own guns that are not registered or to carry guns
3 outside of one’s home or business, requiring background checks for gun purchases, and raising the
4 minimum age for gun purchase to twenty-five. This legislative effort was followed in July 2004 by a
5 campaign to encourage citizens to voluntarily turn in their firearms which netted 450,000 firearms. An
6 examination of firearm-related mortality and hospitalizations trends revealed that, after many years of
7 steady increases, the policies were associated with a significant decline in firearm-related deaths and
8 hospitalizations.⁶⁵

9 52. Although some studies that have examined the effects of Canadian gun control laws
10 have found evidence that the laws reduced firearm suicides but not total suicides as a result of
11 substitution to other highly lethal methods,^{66 67} a thorough analysis of long-term suicide trends which
12 accounts for gradual changes in the age structure of the population in Ontario provided strong
13 evidence that a 1978 law led to a significant decline in suicides in the province that was specific to
14 firearm-related suicides.⁶⁸

15 53. The findings from these studies reveal a consistent pattern. When governments enact
16 measures to reduce the availability of firearms within their jurisdictions, far fewer people die as a
17 result of suicide and homicide. While these policies go well beyond San Francisco’s ordinance
18 requiring handguns kept in a home to be stored in locked containers or with trigger locks, the data
19 demonstrate the connection between gun availability and suicides and homicides. In light of this
20 connection, it is reasonable to believe that reducing the immediate availability of guns, as San
21 Francisco's ordinance does, will also reduce incidents of gun violence.

1 54. Recognizing the risks of unsupervised access of firearms to children and teens, 18
2 states and the District of Columbia have passed laws requiring gun owners to store their firearms in a
3 manner that prevents access to underage youth, typically requiring guns to be stored locked away or
4 with a trigger guard to prevent the gun from firing if handled when locked. In research which I
5 conducted, I found that these so-called child access prevention (CAP) laws are associated with
6 significant reductions in suicides of teens ages 14 – 17 years in the states where they have been
7 adopted.⁶⁹ Cummings and colleagues also examined the effects of CAP laws on suicides and found a
8 negative relationship between presence of a CAP law and suicide risks among youth under age 15.⁷⁰

9 55. There is also evidence that CAP laws intended to required firearm storage which would
10 make firearms either inaccessible or unable to be fired can reduce unintentional shooting deaths of
11 children and teens. Cummings and colleagues conducted the first evaluation of CAP laws and reported
12 that the laws were associated with significant reductions in deaths due to unintentional shootings of
13 youth under age 15. Subsequent research that I conducted with Marc Starnes, as well as a study
14 conducted by Hepburn and colleagues, showed that the effects of CAP laws on unintentional firearm
15 deaths to youth were uneven across states. Reductions were only statistically significant in Florida and
16 California where the laws likely garnered significant publicity.^{71 72} Florida’s law received
17 considerable publicity because it was the first state to pass a CAP law, doing so after a series of highly
18 publicized deaths of children killed in unintentional shootings resulting from underage access to
19 firearms in the home. Florida and California are among the few states where CAP law violators can be
20 charged with a felony crime. The ability for prosecutors to charge CAP law violators with a felony
21 may increase the likelihood of prosecution and increased publicity and awareness of CAP laws.

1 56. Research on the effects of CAP laws in the U.S. have appropriately focused on the
2 effects of the laws on underage youth. San Francisco’s safe gun storage ordinance extends
3 California’s CAP law to all households, regardless of the presence of children or teens, by requiring all
4 handguns to be stored in a locked container or with a trigger lock. In my opinion, it is reasonable to
5 believe that, in light of the relationship between firearm availability and firearm violence discussed
6 throughout this report, the study connecting ease of access to firearms with increased suicide rates, and
7 the problem of gun thefts discussed *infra* in Section IV, requiring locked storage of guns among all
8 households is likely to reduce firearm injuries and deaths. Moreover, San Francisco is particularly
9 justified in enacting this ordinance because U.S. Census data indicate that nearly a third of all
10 households in San Francisco in 2010 included non-family households with adults living with non-
11 family members.⁷³ In such cases, legal possessors of handguns could be sharing a home with a
12 prohibited person who might be able to easily access and use a handgun that was not locked up.

13 57. Some have referenced the work of a review panel of the National Research Council to
14 conclude that there is no scientific evidence that gun control works.⁷⁴ However, this body reviewed a
15 limited set of studies published before 2004, did not consider all policies such as permit-to-purchase
16 licensing systems, and did not examine evaluations of policies implemented outside of the United
17 States. Thus, most of the studies cited above were not included in the committee’s review of the
18 research on the effects of gun control policies.

19 **IV. GREATER FIREARM AVAILABILITY WITHIN HOMES INCREASES THE RISK**
20 **OF HOME BURGLARIES AND OF GUNS ENTERING THE ILLEGAL MARKET**
21 **VIA THEFT.**

22 58. It is my opinion that greater firearm availability within homes increases the risk of
23 home burglaries and of guns entering the illegal market via theft. The research supporting my opinion
24 is described in the following paragraphs.

25 ⁷³ U.S. Census Bureau. American Fact Finder. Household Population and Household Type by
26 Tenure: 2010. 2010 Census Summary File, San Francisco, California. Data indicate that 62,416 of
345,811 households involved nonfamily member adults living in the same household.

28 Improve Research Information and Data on Firearms. Charles F. Welford, John V. Pepper, and Carol
V. Petrie, editors. Committee on Law and Justice, Division of Behavioral and Social Sciences and
Education, Washington, DC: The National Academies Press, 2005.

1 59. Some claim that if more people owned guns there would be a greater deterrent to
2 criminals breaking into homes. However, a careful empirical examination of the data proves that the
3 opposite is true. Economists Phillip Cook and Jens Ludwig analyzed longitudinal burglary data from
4 the Uniform Crime Reports at the state and county levels and cross-sectional data from special
5 restricted-access version of the National Crime Victimization Survey (NCVS) that identified the
6 county in which the survey respondents reside. In the longitudinal analyses they found that a one-year
7 lag of a gun availability proxy (ratio of firearm suicides to all suicides) was positively associated with
8 higher burglary rates with the elasticity of burglaries to gun ownership ranging from around +0.4 to
9 +0.5. Thus, a 10 percent increase in gun ownership would yield a 3 to 7 percent increase in burglary
10 rates. Estimates of the effects of gun ownership on burglaries were very similar in direction and
11 magnitude when the researchers used an instrumental variable for gun ownership rather than the gun
12 suicide proxy.⁷⁵

13 60. A limitation to these analyses is that commercial burglaries are lumped together with
14 residential burglaries in the UCR data. Cook and Ludwig's cross-sectional analyses of NCVS data
15 reveal a strikingly similar positive association between a county's prevalence of gun ownership and
16 the probability that a household reported a home burglary after controlling for characteristics of the
17 household and county. The study also found that, contrary to the view that gun ownership reduces the
18 likelihood that a home is burglarized while someone is at home, there was no statistically significant
19 relationship between county-level gun ownership and the probability that someone was at home during
20 a burglary attempt. The authors argue that the presence of firearms in homes represents attractive loot
21 for criminals, thus providing increased incentives for home burglaries which appear to outweigh the
22 deterrent effects resulting from fears of being shot by a home occupant.

23 61. Data from a nationally-representative survey conducted in the 1990s suggest that as
24 many as 500,000 firearms are stolen each year from U.S. citizens.⁷⁶ A nationally-representative survey

Inducement." Pages 74-120 in *Evaluating Gun Policy*. Jens Ludwig and Philip J. Cook, (eds).
27 Washington, DC: Brookings, 2003.

28 ⁷⁶ Cook PJ, Ludwig J. *Guns in America: Results of a Comprehensive Survey of Gun Ownership
and Use*. Washington, DC: Police Foundation, 1996.

1 of inmates at state prisons from 1997 revealed that 10 percent of firearm offenders had obtained the
2 weapon they had used in crime through theft and another eight percent obtained their gun through a
3 fence or black market source and presumably many of these guns had be stolen from homes.⁷⁷ A more
4 recent study which I conducted used a more recent (2004) survey of prison inmates and revealed very
5 similar findings on the role of theft and street sources in directly supplying criminal offenders with
6 guns.⁷⁸ Thus the findings from Cook and Ludwig’s study of the relationship between gun ownership
7 and burglaries suggest that San Francisco’s current requirements for gun owners to store firearms in
8 the home in a locked container or with a trigger lock would reduce the number of guns available to
9 criminals obtained directly or indirectly through home thefts. Moreover, to the extent that would-be
10 burglars anticipate that firearms will be locked and difficult for them to access, Cook and Ludwig's
11 study suggests that the reduction in this attractive loot may, in turn, reduce the number of burglaries.

12 **V. THERE IS NO RESEARCH THAT SUPPORTS THE NOTION THAT STORING**
13 **UNLOCKED GUNS IN HOMES MAKES OCCUPANTS SAFER.**

14 62. The notion that citizens use guns in self-defense far more commonly than they are
15 victimized by someone with a gun was supported by data from a national survey directed by
16 criminologist Gary Kleck. Kleck and Gertz conducted a national phone survey of 4,977 adults. Fifty-
17 six (1.1%) respondents reported having used defensively used a gun within the past 12 months in
18 situations in which they report being the would-be victim of a crime. The data were used to make a
19 projection that 2.5 million times per year a U.S. citizen used a firearm defensively in situations when
20 someone was committing or attempting to commit a crime.⁷⁹ The projections from this survey are
21 discordant with data from other sources of data relevant to crime and violence, Aside from the fact that
22 the number of defensive gun uses from Kleck and Gertz is 22 times higher than what was estimated
23 from the National Crime Victimization Survey (NCVS), Kleck and Gertz’s data fail tests of external

a gun. *Journal of Criminal Law and Criminology* 1995;86:150-187.

1 validity. For example, Kleck and Gertz data indicate that there are over 200,000 assailants who are
2 wounded by civilians defending themselves against crime each year, yet a national surveillance system
3 for hospital emergency department visits indicate that fewer than 100,000 people are treated for
4 gunshot wounds annually in the United States. Subsequent surveys conducted by Hemenway and
5 colleagues were designed to measure all civilian uses of guns, hostile or aggressive as well as
6 defensive. Their data indicate that, despite a likely bias toward reporting defensive uses of guns that
7 would be viewed favorably and against admitting acts that were criminal behavior, survey respondents
8 more frequently admitted to engaging in aggressive or hostile uses of guns than they did defensive
9 uses of guns. Furthermore, many of the so-called defensive uses are of questionable legality due to
10 inadequate justification for using deadly force.⁸⁰ This finding is far more consistent with the research
11 showing that greater gun availability tends to be associated with higher rates of homicide.

12 63. No prior study of civilian defensive gun use has examined questions most directly
13 relevant to San Francisco's law mandating that firearms in the home be stored in locked containers or
14 with trigger locks.

15 **VI. CONCLUSION**

16 64. San Francisco's safe gun storage ordinance, by limiting the accessibility of firearms to
17 unauthorized users, is likely to benefit public safety by reducing violent deaths within the home and
18 reducing the number of guns obtained by criminals through theft.

19 65. Prior research demonstrates that reducing the availability of firearms in the home,
20 especially reduced availability for unauthorized users such as children and adolescents, decreases the
21 risk for suicide, homicide, and deaths from unintentional shootings. Risks of violent death within the
22 home of gun owners are reduced by safe storage practices such as locking up guns. Such storage
23 practices would reduce availability of operable firearms available to an unauthorized household
24 member when he or she becomes distraught, suicidal, angry, or otherwise lose control of his or her
25 emotions and thus lead to fewer tragic deaths. Furthermore, the law should reduce the number of guns
26 which are stolen and then enter the illegal market.
